Advanced Coupling Matrix Synthesis Techniques for Microwave Filters

Richard J. Cameron, Fellow, IEEE

Abstract—A general method is presented for the synthesis of the folded-configuration coupling matrix for Chebyshev or other filtering functions of the most general kind, including the fully canonical case, i.e., $N$ prescribed finite-position transmission zeros in a network. The method is based on the $N + 2$ transversal network coupling matrix, which is able to accommodate multiple input/output couplings, as well as the direct source-load coupling needed for the fully coupled cases. Firstly, the direct method for building up the coupling matrix for the transversal network is described. A simple nonoptimization process then yields the conversion of the transversal matrix to the equivalent $N + 2$ folded-configuration coupling matrix. The folded matrix may be used directly to realize microwave bandpass filters in a variety of technologies, but some of these could be awkward to realize cross-couplings. This paper concludes with a description of two simple procedures for transforming the transversal and folded matrices into two novel network configurations which enable the realization of advanced microwave bandpass filters without the need for complex inter-resonator coupling elements.

Index Terms—Asymmetric filtering functions, Chebyshev characteristics, circuit synthesis methods, coupling matrix, microwave filters, transversal network.

I. INTRODUCTION

In [1], a recursive method for deriving the transfer and reflection polynomials for Chebyshev filtering functions with prescribed finite-position transmission zeros (FTZs) was presented. This was followed by the synthesis methods for the corresponding $N \times N$ coupling matrix, ready for the design of a microwave filter with resonators arranged as a folded cross-coupled array. It was mentioned in [1] that the polynomial synthesis procedure was capable of realizing $N$ TZs for an $N$th-degree network (i.e., fully canonical), that a maximum of only $N - 2$ finite-position could be realized by the $N \times N$ coupling matrix. This added some useful filtering characteristics, including those require multiple input/output couplings, which have been used in applications recently [3].

In this paper, a method is presented for the synthesis of the $N$th canonical or $N + 2$ folded coupling matrix, which overcomes some of the shortcomings of the conventional $N \times N$ coupling matrix. The $N + 2$ or "extended" coupling matrix has extra pair of rows on top and bottom and one extra pair of columns and right surrounding the "core" $N \times N$ coupling matrix. It carries the input and output couplings from the source and terminations to the resonator nodes in the core matrix. The $N + 2$ matrix has the following advantages, as compared with the conventional coupling matrix.

- Multiple input/output couplings may be accommodated, i.e., couplings may be made directly from the source and/or the load to internal resonators, in addition to the main input/output couplings to the first and last resonator in the filter circuit.
- Fully canonical filtering functions (i.e., $N$th-degree characteristics with $N$ finite-position TZs) may be synthesized.
- During certain synthesis procedures that employ a sequence of similarity transforms (rotations), it is sometimes convenient to temporarily "park" couplings in the outer rows or columns, whilst other rotations are carried out elsewhere in the matrix.

The paper begins by detailing the procedure for synthesizing the $N + 2$ coupling matrix from the transversal array circuit representation of the filtering function (see Figs. 1(a) and 2), which follows on from the methods originally established in [4]-[7] and later extended in [1]. The new method is actually simpler to derive than those used to synthesize the $N \times N$ coupling matrix, not requiring the Gram–Schmidt orthonormalization stage. The
reduction of the transversal coupling matrix to the \(N + 2\) folded cross-coupled array coupling matrix is then outlined, following much the same procedure as in [1]. A demonstration of the use of the techniques to synthesize the coupling matrix for a fully canonical filtering function is included.

Finally, the direct synthesis of two novel filter configurations are presented; one starting with the transversal coupling matrix and the second based on the folded coupling matrix. Both are applicable to the design of microwave band-pass filters in a variety of technologies, but the second, in particular, has some important implementation advantages that should considerably ease the design and production of high performance filters for space or terrestrial communications systems.

II. SYNTHESIS OF THE "\(N + 2\)" TRANSVERSAL COUPLING MATRIX

The approach that will be employed to synthesize the \(N + 2\) transversal coupling matrix will be to construct the two-port short-circuit admittance parameter matrix \(Y_N\) for the overall network in two ways: the first from the coefficients of the rational polynomials of the transfer and reflection scattering parameters \(S_{21}(s)\) and \(S_{11}(s)\), which represent the characteristics of the filter to be realized, and the second from the circuit elements of the transversal array network. By equating the \(Y_N\) matrices as derived by these two methods, the elements of the coupling matrix associated with the transversal array network may be related to the coefficients of the \(S_{21}(s)\) and \(S_{11}(s)\) polynomials.

A. Synthesis of Admittance Function \(Y_N\) From the Transfer and Reflection Polynomials

The transfer and reflection polynomials that are generated in [1] for the general Chebyshev filtering function are in the form

\[
S_{21}(s) = \frac{P(s)}{\varepsilon E(s)} \quad S_{11}(s) = \frac{F(s)}{\varepsilon_{R} E(s)}
\]

where \(\varepsilon = \left(1/\sqrt{10^{RL/10} - 1}\right)\cdot (P(s)/F(s))\), \(RL\) is the prescribed return loss in decibels, and it is assumed that the polynomials \(E(s), F(s),\) and \(P(s)\) have been normalized to their respective highest degree coefficients. Both \(E(s)\) and \(F(s)\) are \(N\)-th degree polynomials, \(N\) is the degree of the filtering function, while \(P(s)\), which contains the finite-position prescribed T\(Z\)s, is of degree \(n_E\), where \(n_E\) is the number of finite-position T\(Z\)s that have been prescribed. For a realizable network, \(n_E\) must be \(\leq N\).

\(\varepsilon_{R}\) is unity for all cases except for fully canonical filtering functions, where all the T\(Z\)s are prescribed at finite frequencies, i.e., \(n_E = N\). In this case, the value of \(S_{21}(s)\) (in decibels) is finite at infinite frequency, and if the highest degree coefficient of the polynomials \(E(s), F(s),\) and \(P(s)\) are each normalized to unity, \(\varepsilon_{R}\) will have a value slightly greater than unity as follows:

\[
\varepsilon_{R} = \frac{\varepsilon}{\sqrt{\varepsilon^2 - 1}}.
\]

It is also important to ensure that the transfer and reflection vectors are orthogonal in order to satisfy the unitary conditions for the scattering matrix [8]

\[
S_{11} \cdot S_{11}^\ast + S_{21} \cdot S_{21}^\ast = 1
\]

\[
S_{21} \cdot S_{21}^\ast + S_{12} \cdot S_{12}^\ast = 1
\]

\[
S_{11} \cdot S_{12} + S_{21} \cdot S_{22} = 0.
\]

From (3), it may be shown (see [2, p. 177]) that the phases \(\phi_1, \theta_1,\) and \(\theta_2\) of the vectors \(S_{21}(s), S_{11}(s),\) and \(S_{22}(s),\) respectively, are related by the following:

\[
\phi - \theta_1 + \theta_2 = \Delta_\phi = \frac{\pi}{2} (2k + 1)
\]

where \(k\) is an integer.

Equation (4) shows that the difference \(\Delta_\phi\) between the phase of the \(S_{21}\) vector, and the average of the phases of the \(S_{11}\) and \(S_{22}\) vectors must be an odd multiple of \(\pi/2\) rad. For this condition to be satisfied at any value of the frequency variable \(s\), the \(n_E\) T\(Z\)s of \(S_{21}(s)\) must be positioned symmetrically about the imaginary \((j\omega)\) axis or on the imaginary axis itself. Similarly, the pattern of the \(N\) zeros of \(S_{22}(s)\) must either be coincident with those of \(S_{11}(s)\) on the imaginary axis, or form mirror-image pairs about the imaginary axis with corresponding off-axis zeros of \(S_{11}(s)\). In this way, the sum of the phases of the individual vectors that make up the overall phases of the vectors \(S_{21}, S_{11}, \) etc., will be multiples of \(\pi/2\) rad.

Since \(S_{21}(s), S_{11}(s),\) and \(S_{22}(s)\) share a common denominator polynomial \(E(s),\) it is only necessary to consider their numerator polynomials as far as (4) is concerned. The multiples of \(\pi/2\) rad referred to above therefore depend upon the number of finite-position transmit (Tx) zeros \(n_T\), for the \(S_{21}(s)\) numerator polynomial \(P(s),\) and the degree \(N\) of the filtering function for the \(S_{11}(s)\) and \(S_{22}(s)\) numerator polynomials \(F(s)\) and \(F^\ast(s),\) respectively. With this in mind, it follows that, for the left-hand side of (4) to produce an odd multiple of \(\pi/2\) rad, the integer quantity \(N - n_T\) must itself be odd. Thus, to ensure orthogonality between the \(F(s)\) and \(F^\ast(s)\) vectors, i.e., \(\Delta_\phi\) is an odd multiple of \(\pi/2\) rad, it is necessary to multiply the \(P(s)\) polynomial by \(j\) whenever \(N - n_T\) is an even integer.
The numerator and denominator polynomials for the \( y_{21}(s) \) and \( y_{22}(s) \) elements of \( [Y_X] \) may be built up directly from the transfer and reflection polynomials for \( S_{21}(s) \) and \( S_{11}(s) \) [1]. For a double-terminated network with source and load terminations of \( 1 \Omega \)

\[
y_{22}(s) = \frac{y_{22n}(s)}{y_a(s)} = n_1(s)/m_1(s)
\]

and

\[
y_{21}(s) = \frac{y_{21n}(s)}{y_a(s)} = \left( P(s)/\varepsilon \right)/m_1(s), \text{ for } N \text{ even}
\]

\[
y_{22}(s) = \frac{y_{22n}(s)}{y_a(s)} = m_1(s)/n_1(s)
\]

and

\[
y_{21}(s) = \frac{y_{21n}(s)}{y_a(s)} = \left( P(s)/\varepsilon \right)/n_1(s), \text{ for } N \text{ odd}
\]

where

\[
m_1(s) = \text{Re}(r_0 + f_0) + j \text{Im}(e_1 + f_1)s + \text{Re}(r_2 + f_2)s^2 + \ldots
\]

\[
n_1(s) = j \text{Im}(e_1 + f_0) + \text{Re}(e_1 + f_1)s + \text{Im}(e_2 + f_2)s^2 + \ldots
\]

(5)

and \( r_i, f_i, t = 0, 1, 2, \ldots, N \) are the complex coefficients of \( E(s) \) and \( F(s)/\varepsilon \), respectively. The \( y_{21}(s) \) and \( y_{22}(s) \) polynomials for single-terminated networks may be found by a similar procedure [1].

Knowing the denominator and numerator polynomials for \( y_{21}(s) \) and \( y_{22}(s) \), their residues \( r_{21k} \) and \( r_{22k} \), \( k = 1, 2, \ldots, N \) may be found with partial fraction expansions, and the purely real eigenvalues \( \lambda_k \) of the network found by rooting the denominator polynomial \( y(s) \) common to both \( y_{21}(s) \) and \( y_{22}(s) \), which has purely imaginary roots \( = \pm j\lambda_k \) (see [1, Appendix]). Expressing the residues in matrix form yields the following equation for the admittance matrix \( [Y_X] \) for the overall network:

\[
[Y_X] = \begin{bmatrix}
y_{11}(s) & y_{12}(s) \\
y_{21}(s) & y_{22}(s)
\end{bmatrix}
\]

\[
= \frac{1}{y_a(s)} \begin{bmatrix}
y_{11n}(s) & y_{12n}(s) \\
y_{21n}(s) & y_{22n}(s)
\end{bmatrix}
\]

\[
= j \begin{bmatrix}
0 & K_0 \\
K_0 & 0
\end{bmatrix} + \sum_{k=1}^{N} \frac{1}{s-j\lambda_k} \begin{bmatrix}
r_{11k} & r_{12k} \\
r_{21k} & r_{22k}
\end{bmatrix}
\]

(6)

where the real constant \( K_0 = 0 \), except for the fully canonical case where the number of finite-position TZs \( n_{TP} \) in the filtering function is equal to the filter degree \( N \). In this case, the degree of the numerator of \( y_{21}(s) \) \( y_{21n}(s) = jP(s)/\varepsilon \) is equal to its denominator \( y_a(s) \), and \( K_0 \) has to be extracted from \( y_{22}(s) \) \( = y_{12}(s) \) first to reduce the degree of its numerator polynomial \( y_{21}(s) \) by one before its residues \( r_{21k} \) may be found. Note that, in the fully canonical case, where the integer quantity \( N \) \( = n_{TP} \leq 0 \) is even, it is necessary to multiply \( P(s) \) by \( j \) to ensure that the unitary conditions for the scattering matrix are satisfied.

Refractive independent of \( \varepsilon \), \( K_0 \) may be evaluated at \( \varepsilon = j\infty \) as follows:

\[
jK_0 = \frac{y_{21n}(s)}{y_a(s)} \bigg|_{\varepsilon = j\infty} = \left. \frac{P(s)}{y_a(s)} \right|_{\varepsilon = j\infty}.
\]

(7)

The process for building up \( y_a \) (see (5)) results in its highest degree coefficient having a value of \( 1 + 1/\varepsilon \) \( R \) and, since the highest degree coefficient of \( P(s) = 1 \), the value of \( K_0 \) may be found as follows:

\[
K_0 = \frac{1}{\varepsilon} \left( 1 + \frac{1}{\varepsilon R} \right) \frac{1}{\varepsilon (\varepsilon R + 1)}.
\]

(8)

The new numerator polynomial \( y_{21n}(s) \) may now be determined as follows:

\[
y_{21n}(s) = y_{21n}(s) - jK_0 y_a(s)
\]

(9)

which will be of degree \( N - 1 \), and the residues \( r_{21k} \) of \( y_{21}(s) = y_{21a}(s)/y_a(s) \) may now be found as normal.

B. Synthesis of Admittance Function \([Y_X] - [Circuit Approach]

The two-port short-circuit admittance parameter matrix \( [Y_X] \) for the overall network may also be synthesized directly from the fully canonical transversal network, the general form of which is shown in Fig. 1(a). It comprises a series of \( N \) individual first-degree low-pass sections, connected in parallel between the source and load terminations, but not to each other. The direct source-load coupling inverter \( M_{SL} \) is included to allow fully canonical transfer functions to be realized, according to the "minimum path" rule, i.e., \( n_{TP,\text{max}} \), the maximum number of finite position TZs that may be realized by the network = \( N - n_{\text{min}} \), where \( n_{\text{min}} \) is the number of resonators in the shortest route through the network between the source and load terminations. In fully canonical networks \( n_{\text{min}} = 0 \), and thus, \( n_{TP,\text{max}} = N \), the degree of the network.

Each of the \( N \) low-pass sections comprises one parallel-connected capacitor \( C_k \) and one frequency invariant susceptance \( B_k \), connected through admittance inverters of characteristic admittances \( M_{SL} \) and \( M_{LK} \) to the source and load terminations, respectively. The circuit of the \( k \)th low-pass section is shown in Fig. 1(b).

Fully Canonical Filtering Functions

The direct source-load inverter \( M_{SL} \) in Fig. 1(a) is zero except for fully canonical filtering functions, where the number of finite-position zeros equals the degree of the filter. At infinite frequency \( (s = \pm j\infty) \), all the capacitors \( C_k \) become parallel short circuits, which appear as open circuits at the source-load ports through the inverters \( M_{SL} \) and \( M_{LK} \). Thus, the only path between source and load is via the frequency-invariant admittance inverter \( M_{SL} \).

If the load impedance is \( 1 \Omega \), the driving point admittance \( Y_{11\infty} \) looking in at the input port will be (Fig. 3)

\[
Y_{11\infty} = M_{SL}^2.
\]

Therefore, the input reflection coefficient \( S_{11}(s) \) at \( s = j\infty \) is

\[
S_{11}(s)|_{s=j\infty} = |S_{11\infty}| = \frac{(1 - Y_{11\infty})}{(1 + Y_{11\infty})}.
\]

(10)

Substituting for \( |S_{11\infty}| \) in the conservation of energy equation using (10)

\[
|S_{21\infty}| = \sqrt{1 - |S_{11}\infty|^2} = \frac{2\sqrt{Y_{11\infty}}}{(1 + Y_{11\infty})} = \frac{2M_{SL}}{(1 + M_{SL}^2)}.
\]
Solving for $M_{SL}$

$$M_{SL} = \frac{1 \pm \sqrt{1 - \left| S_{21\infty} \right|^2}}{\left| S_{21\infty} \right|} = \frac{1 \pm S_{21\infty}}{S_{21\infty}}.$$ 

At infinite frequency $|S_{21}(j\infty)| = \frac{|P(j\in\infty)/E(j\in\infty)|}{1/\varepsilon}$ because, for a fully canonical filtering function, $P$ and $E$ will both be $N$th-degree polynomials with their highest degree coefficients normalized to unity. Similarly, $|S_{21}(j\infty)| = \frac{|P(j\in\infty)/E(j\in\infty)|}{1/\varepsilon} = 1/\varepsilon$. Therefore,

$$M_{SL} = \varepsilon R \pm \frac{1}{\varepsilon}$$

Since $\varepsilon R$ is slightly greater than unity for a fully canonical network, choosing the negative sign will give a relatively small value for $M_{SL}$.

$$M_{SL} = \varepsilon R - \frac{1}{\varepsilon}$$

and correctly gives $M_{SL} = 0$ for noncanonical filters, where $\varepsilon R - 1$. It can be shown that the positive sign will give a second solution $M_{SL} = 1/\varepsilon R$, but since this will be a large number, it is never used in practice [8].

**Synthesis of Two-Port Admittance Matrix $[Y_N]$**

Cascading the elements in Fig. 1(b) gives an ABCD transfer matrix for the $kth$ “low-pass resonator” as follows:

$$[ABCD]_{k-1} = \begin{bmatrix} M_{Lk} & M_{Sk} M_{Lk} \\ M_{Sk} & M_{Lk} \\ 0 & M_{Sk} \\ 0 & M_{Lk} \end{bmatrix}$$

which may then be directly converted into the equivalent short-circuit $y$-parameter matrix

$$[yk] = \begin{bmatrix} y_{11k}(s) & y_{12k}(s) \\ y_{21k}(s) & y_{22k}(s) \end{bmatrix} = \frac{M_{Sk} M_{Lk}}{(sC_k + jB_k)} \begin{bmatrix} M_{Lk} & 1 \\ 1 & M_{Sk} \end{bmatrix}$$

$$= \frac{1}{(sC_k + jB_k)} \begin{bmatrix} M_{Sk}^2 & M_{Sk} M_{Lk} \\ M_{Sk} M_{Lk} & M_{Lk}^2 \end{bmatrix}$$

The two-port short-circuit admittance matrix $[y_N]$ for the parallel-connected transverse array is the sum of the $y$-parameter matrices for the $N$ individual sections, plus the $y$-parameter matrix for the direct source-load coupling inverter $M_{SL}$.

$$[Y_N] = \begin{bmatrix} y_{11}(s) & y_{12}(s) \\ y_{21}(s) & y_{22}(s) \end{bmatrix} + \sum_{k=1}^{N} \begin{bmatrix} y_{11k}(s) & y_{12k}(s) \\ y_{21k}(s) & y_{22k}(s) \end{bmatrix}$$

$$= \begin{bmatrix} 0 & M_{SL} \\ M_{SL} & 0 \end{bmatrix} + \sum_{k=1}^{N} \frac{1}{(sC_k + jB_k)} \begin{bmatrix} M_{Sk}^2 & M_{Sk} M_{Lk} \\ M_{Sk} M_{Lk} & M_{Lk}^2 \end{bmatrix}$$

**C. Synthesis of the $N + 2$ Transversal Matrix**

Now the two expressions for $[Y_N]$, the first in terms of the residues of the transfer function $[6]$, and the second in terms of the circuit elements of the transversal array $[14]$, may be equated. It may be seen immediately that $M_{SL} = R_0$, and for the “21” and “22” elements in the matrices in the right-hand side of (6) and (14)

$$\frac{r_{21k}}{(s-j\lambda_k)} = \frac{M_{Sk} M_{Lk}}{(sC_k + jB_k)}$$

$$\frac{r_{22k}}{(s-j\lambda_k)} = \frac{M_{Lk}^2}{(sC_k + jB_k)}$$

The residues $r_{21k}$ and $r_{22k}$ and the eigenvalues $\lambda_k$ have already been derived from the $S_{21}$ and $S_{22}$ polynomials of the desired filtering function [see (5)] and, thus, by equating the real and imaginary parts in (15a) and (15b), it becomes possible to relate them directly to the circuit parameters

$$C_k = 1 \text{ and } B_k (= M_{Lk}) = -\lambda_k$$

$$M_{Lk}^2 = r_{22k} \text{ and } M_{Sk} M_{Lk} = r_{21k}$$

$$M_{Lk} = \sqrt{r_{22k}} = T_{Nk} \quad k = 1, 2, \ldots, N$$

It may be recognized at this stage that $M_{Sk}$ and $M_{Lk}$ constitute the unscattered row vectors $T_{1k}$ and $T_{Nk}$ of the orthogonal matrix $[T]$, as defined in (1, Appendix).

Since the capacitors $C_k$ of the parallel networks are all unity, and the frequency-invariant components $R_k (= -\lambda_k$, representing the self couplings $M_{11} \to M_{NN}$), the input couplings $M_{Sk}$, the output couplings $M_{Lk}$, and the direct source-load coupling $M_{SL}$ are all now known, the reciprocal $N + 2$ transversal coupling matrix $[M]$ representing the network in Fig. 1(a) may now be constructed. $M_{Sk} (= T_{1k})$ are the $N$ input couplings and occupy the first row and column of the matrix from positions 1 to $N$ (see Fig. 2). Similarly, $M_{Lk} (= T_{Nk})$ are the $N$ output couplings and occupy the last row and column of $[M]$ from positions 1 to $N$. All other entries are zero. $M_{Sk}^2$ and $M_{Lk}^2$ are equivalent to the terminating impedances $R_1$ and $R_N$, respectively, in [1].
and these are shown in Table I. Being fully canonical, \( \varepsilon_R \neq 1 \) and may be found from (2). Note that, because \( N - n_{LT} = 0 \) and is, therefore, an even number, the coefficients of \( P(s) \) have been multiplied by \( j \) in Table I.

Now the numerator and denominator polynomials of \( y_{21_1}(s) = y_{21_1}(s)/y_{21_2}(s) \) and \( y_{22_1}(s) = y_{22_1}(s)/y_{21_2}(s) \) may be constructed using (5). The coefficients of \( y_{21_1}(s) \), \( y_{22_1}(s) \), and \( y_{22_2}(s) \), normalized to the highest degree coefficient of \( y_{21_1}(s) \), are summarized in Table II.

The next step is to find the residues of \( y_{21_1}(s) \) and \( y_{22_1}(s) \) with partial fraction expansions. Since the numerator of \( y_{22_1}(s) \) \( y_{22_1}(s) \) is one less in degree than its denominator \( y_{21_1}(s) \), finding the associated residues \( r_{22_k} \) is straightforward. However, the degree of the numerator of \( y_{22_1}(s) \) \( y_{22_1}(s) \) is the same as its denominator \( y_{21_1}(s) \), and the factor \( K_0 \ (= M_{SL}) \) has to be extracted from to reduce \( y_{21_1}(s) \) in degree by one.

This is easily accomplished by first finding \( M_{SL} \) by evaluating \( y_{21_1}(s) \) at \( s = j\infty \), i.e., \( M_{SL} \) equals the ratio of the highest degree coefficients in the numerator and denominator polynomials of \( y_{21_1}(s) \) [see (7) and (8)] as follows:

\[
jM_{SL} = \left. y_{21_1}(s) \right|_{s=j\infty} = \left. \frac{b_{21_1}(s)}{y_{21_1}(s)} \right|_{s=j\infty} = 0.01509
\]

which may be seen is the highest degree coefficient of \( y_{21_1}(s) \) in Table II. Alternatively, \( M_{SL} \) may be derived from (11).

\( M_{SL} \) may now be extracted from the numerator of \( y_{21_1}(s) \) [see (9)] as follows:

\[
y_{22_1}(s) = \left. y_{21_1}(s) \right|_{s=j\infty} - jM_{SL}y_{21_2}(s).
\]

At this stage, \( y_{21_1}(s) \) will be one degree less than \( u_{21}(s) \) and the residues \( r_{22_k} \) may be found as normal. The residues, the eigenvalues \( \lambda_k \) [where \( j\lambda_k \) are the roots of \( y_{21_1}(s) \)], and the associated eigenvectors \( T_{1k} \) and \( T_{2k} \) are listed in Table III.

Note that, for double-terminated lossless networks with equal source and load terminations, \( r_{21_1} \) will be positive real for a realizable network, and \( |r_{21_1}| = |r_{22_1}| \).

Now knowing the values of the eigenvalues \( \lambda_k \), the eigenvectors \( T_{1k} \) and \( T_{2k} \), and \( M_{SL} \), the \( N + 2 \) transversal coupling matrix (Fig. 2) may be completed as shown in Fig. 5.

Using the same reduction process as described in [1], but operating upon the \( N + 2 \) matrix, the transversal matrix may be reduced to the folded form with a series of six rotations, annihilating the elements \( M_{SL}, M_{ST}, M_{ST}, M_{SR}, M_{SR}, \) and \( M_{SR} \) in order (see Table IV). The resulting folded configuration coupling matrix is shown in Fig. 6(a), and its corresponding coupling and routing schematic is shown in Fig. 6(b).

The analysis of this coupling matrix is shown in Fig. 7. It may be seen that the return loss and rejection characteristics are unchanged from those obtained from the analysis of the original \( S_{11} \) and \( S_{21} \) polynomials.

### III. Transformations of the Coupling Matrix

A microwave filter may be realized directly from the folded coupling matrix, the topology and strengths of its inter-resonator couplings directly corresponding to the nonzero elements of the coupling matrix. However, it is sometimes necessary to apply

(a)

(b)

Fig. 6. Fully canonical synthesis example. Folded coupling matrix for a 4-4 filtering function. (a) Coupling matrix. Matrix is symmetric about the principal diagonal. (b) Coupling and routing schematic.

Here, two novel realizations are introduced; parallel-connected two-port networks and the "cul-de-sac" configuration. The first may be derived by grouping residues and forming separate two-port subnetworks, which are then connected in parallel between the source and load terminations. The second is formed by a series of similarity transforms operating upon the folded coupling matrix.

a further series of rotations to the matrix, to transform it into a form more convenient or more practical to the application in hand, e.g., [10]-[12].
Grouping residues \( k = 1 \) and \( 6 \) yields the folded matrix for the second-degree subnetwork shown in Fig. 8. Now grouping residues \( k = 2, 3, 4, \) and \( 5 \) yields the folded coupling matrix for the fourth-degree subnetwork shown in Fig. 9.

Superimposing the two matrices yields the overall matrix shown in Fig. 10.

The results of analyzing the overall coupling matrix are shown in Fig. 11(a) (rejection/return loss) and Fig. 11(b) (group delay), which show that the 25-dB low level and equalized in-band group delay have been preserved.

Other solutions for this topology are available depending on the combinations of residues that are chosen for the subnetworks. However, whatever combination is chosen, at least one of the input/output couplings will be negative. Of course, the number of topology options increases as the degree of the filtering function increases, for example, a tenth-degree tilter may be realized as two parallel-connected two-port networks, one fourth degree and one sixth degree, or as three networks, one second degree and two fourth degree, all connected in parallel between the source and load terminations. Also, each subnetwork itself may be reconfigured to other two-port topologies with further transformations if possible.

If the network is to be synthesized as \( N/2 \) parallel-coupled pairs (see Fig. 12 for a sixth-degree example), a rather more direct synthesis route exists. Starting with the transversal matrix, it is only necessary to apply a series of rotations to annihilate half the couplings in the top row from positions \( M_{6, N} \) back to the midpoint of this row \( M_{N/2+1, N/2} \), i.e., \( N/2 \). (See Fig. 2). Due to the symmetry of the values in the outer rows and columns of the transversal matrix, the corresponding entries \( M_{1, N} \) to \( M_{N/2, L} \) in the last column will be annihilated simultaneously.

The pivots of the rotations to annihilate these couplings start at position \([1, N]\) and progress toward the center of the matrix until position \([N/2, N/2 + 1]\). For the sixth-degree example, this is a sequence of \( N/2 \) rotations according to Table V which is applied to the transversal matrix.

After the series of rotations, the matrix, as shown in Fig. 12(a), is obtained, which corresponds to the coupling and routing diagram in Fig. 12(b). In every case, at least one of the input/output couplings will be negative. An interesting example of a fourth-degree implementation of this topology realized in dielectric resonator technology is given in [13].

B. "Cul-de-Sac" Configurations

The "cul-de-sac" configuration [14] is restricted to double-terminated networks and will realize a maximum of \( N - 3 \) TZs. Otherwise it will accommodate even- or odd-degree symmetric or asymmetric prototypes. It has an important advantage over other configurations in that, whatever the prototype filtering function, there will be only one negative coupling in the entire network and there will be no "diagonal" cross-couplings, which are sometimes awkward to realize in practice. Moreover, its form lends itself to a certain amount of flexibility in the physical layout of its resonators.

A typical "cul-de-sac" configuration is shown in Fig. 13(a) for a tenth-degree prototype with the maximum-allowable seven Tx zeros (in this case, three imaginary-axis and two complex pairs). There is a central "core" of a quarter of resonators in a square

is always negative; the choice of which one is arbitrary. The entry to and exit from the core quartet are from opposite corners of the square [1 and 10, respectively, in Fig. 13(a)].

Some of all of the rest of the resonators are strung out in cascade from the other two corners of the core quartet in equal numbers (even-degree prototypes) or one more than the other (odd-degree prototypes). The last resonator in each of the two chains has no output coupling, hence, the nomenclature “cul-de-sac” for this configuration. Other possible configurations are shown in Fig. 13(b) (eighth degree) and Fig. 13(c) (seventh degree).

C. Synthesis of the “Cul-de-sac” Network

Fortunately, the synthesis of the “cul-de-sac” network is very simple and is entirely automatic. Starting with the folded coupling matrix, elements are annihilated using a series of regular similarity transforms (for odd-degree filters), and “cross-pivot” transforms (for even-degree filters), beginning with a main line coupling near the center of the matrix, and working outwards along or parallel to the antidiagonal. This gives a maximum of $(N-2)/2$ transforms for even degree prototypes and $(N-3)/2$ for odd-degree prototypes.

The “cross-pivot” similarity transform for even-degree filters is one where the coordinates of the pivot to be eliminated are the same as the pivot of the transform, i.e., the pivot to be annihilated lies on the cross-points of the pivot. The angle for the annihilation of an element at the cross-point is different to that of a regular annihilation and is given by

$$\theta_t = \frac{1}{2}\tan^{-1}\left[\frac{2M_{ij}}{c(M_{ij} - M_{ss})}\right] + \frac{k\pi}{2}$$  \hspace{1cm} (17)

where $i, j$ are the coordinates of the pivot and also of the element to be annihilated, $\theta_t$ is the angle of the similarity transform, and $k$ is an arbitrary integer. Note that for cross-pivot annihilations of $M_{ij}$ ($\neq 0$), where the self-couplings $M_{ii}, M_{jj}$, $\theta_t = \pm \pi/4$. It is also allowable to have $\theta_t = \pm \pi/4$ for when $M_{ij} = 0$, which will give a slightly different configuration alternative. For odd-degree filters, the angle formula takes the more conventional form

$$\theta_t = \tan^{-1}\left(M_{ij} - M_{ss}/c(M_{ij} - M_{ss})\right)$$  \hspace{1cm} (18)

Table VII gives the pivot coordinates and angle formula to be used for the sequence of similarity transforms to be applied to the folded coupling matrix for degrees $\geq 4$, and a general formula for the pivot coordinates for any degree $\geq 4$.

An example is made of the double-terminated version of the seventh-degree prototype that was used in [1]. This characteristic had 23-dB return loss, a TZ at $+j1.2576$ to give a rejection lobe level of 30 dB on the upper side of the passband, and a complex pair of Tx zeros at $+0.9218 - j0.1546$ to give group-delay equalization over approximately 69% of the passband.

After following the procedure of Section II, the $(N+2)$ folded matrix shown in Fig. 14(a) is obtained. Applying a series of two similarity transforms at pivots [3, 4] and [2, 6] (Table VII) with angles according to (18) results in the coupling matrix of Fig. 14(b). The corresponding coupling and routing diagram is given in Fig. 13(c).
to employ. Two examples of such reconfigurations are included in the paper, the parallel-coupled two-port network configuration and the "cul-de-sac" filter configuration. The latter features some important constructional simplifications that should reduce the volume production process for high-performance microwave filters for the wireless industry.

ACKNOWLEDGMENT

The author is grateful to Dr. J. D. Rhodes, Filtonics plc, Saltaire, U.K., and Dr. C. Ernst, Lorch Microwave Inc., Salisbury, MD for useful discussions that aided considerably in the development of the theory presented in this paper.  

REFERENCES

IV. CONCLUSIONS

In this paper, a simple and general method for the synthesis of the \( N + 2 \) coupling matrix in the folded cross-coupled array configuration has been presented. The \( N + 2 \) coupling matrix is applicable to symmetric or asymmetric, single- or double-terminated, and even- or odd-degree filtering functions, and will accommodate the fully canonical and multiple-input/output coupling configurations.

The \( N + 2 \) folded coupling matrix may be used directly for the design of a microwave filter if it is convenient to do so, or used as the starting point for the application of a further series of similarity transforms to reconfigure it into a topology more convenient for the technology or production process it is intended

Richard J. Cameron (M'83-SM'94-F'02) was born in Glasgow, U.K., in 1947. He received the B.Sc. degree in telecommunications and electronic engineering from Loughborough University, Loughborough, U.K., in 1969.

In 1969, he joined Marconi Space and Defence Systems, Stanmore, U.K. His activities there included small earth-station design, telecommunication satellite system analysis, and computer-aided RF circuit and component design. In 1975, he joined the European Space Agency's (ESA) The Netherlands, where he was involved in the research and development of advanced microwave active and passive components and circuits, with applications in telecommunications, scientific, and earth observation spacecraft. Since joining COM DEV International Ltd., Aylesbury, U.K., in 1984, he has been involved in the software and methods for the design of a wide range of high-performance components and subsystems for both space and terrestrial applications.

Mr. Cameron is a Fellow of the Institution of Electrical Engineers (IEEE), U.K.
