View Controllers

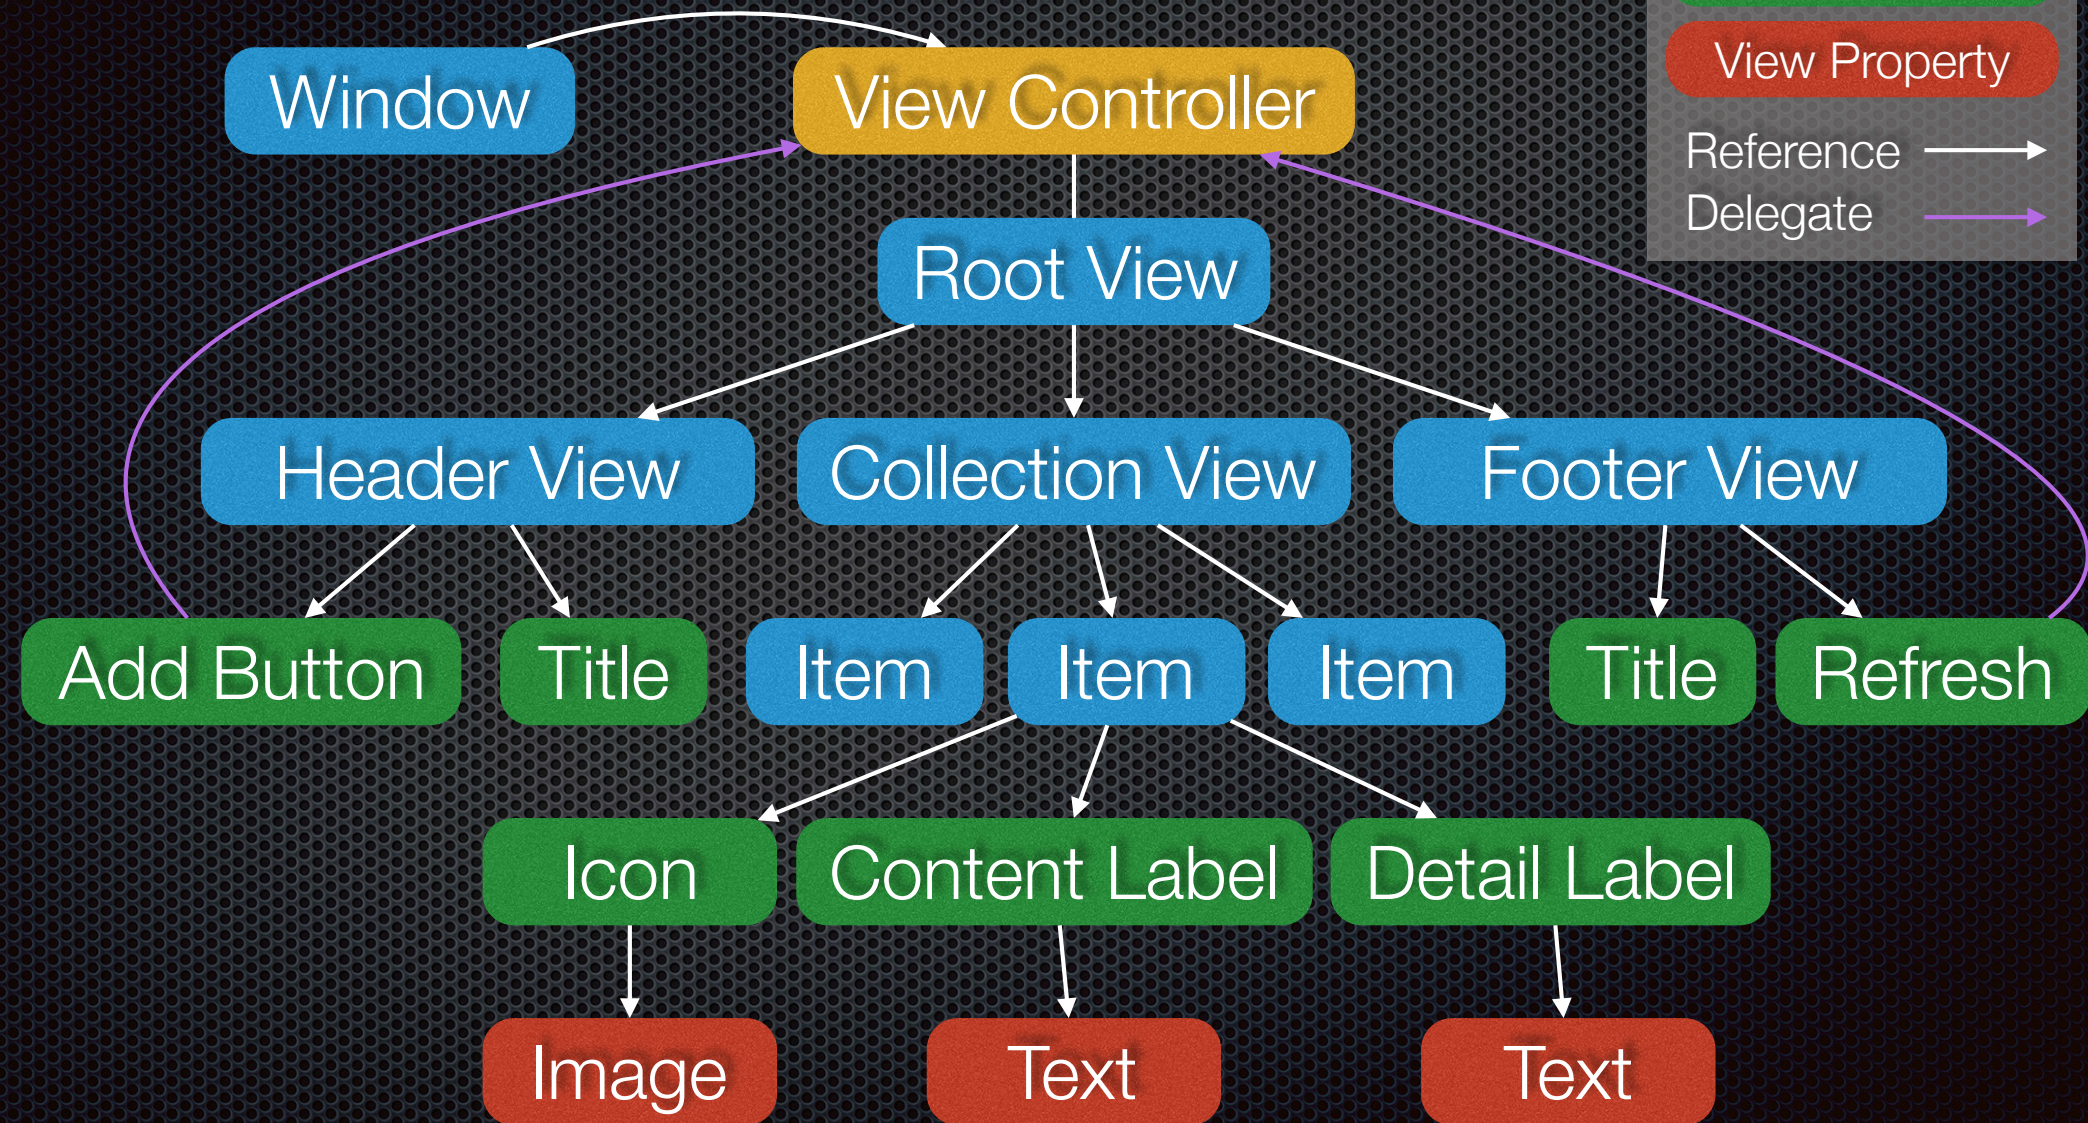

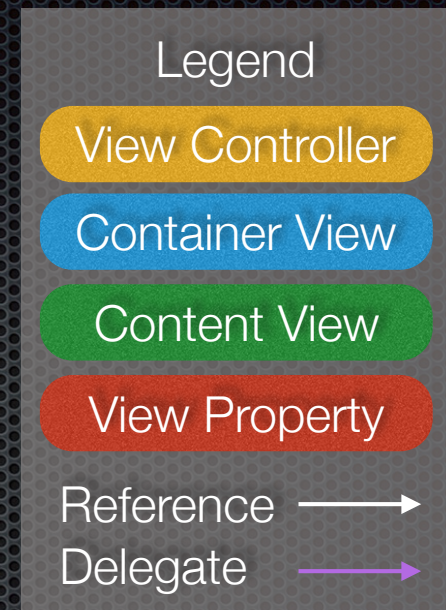

View Controllers

- ✦ Act as **controllers** in the MVC object relationship
 - ✦ They are not the only kind of controllers in an app
 - ✦ Typically occupy the location just above **views** in an application's object hierarchy
- ✦ Manage a **view hierarchy** by way of a **single view**
- ✦ Responds to view **events** using the **target-action** mechanism and **delegate** relationships
- ✦ Effect changes in **model** objects either directly or by communicating with other **controller** objects

Object Graphs

Automatic Reference Counting (ARC)

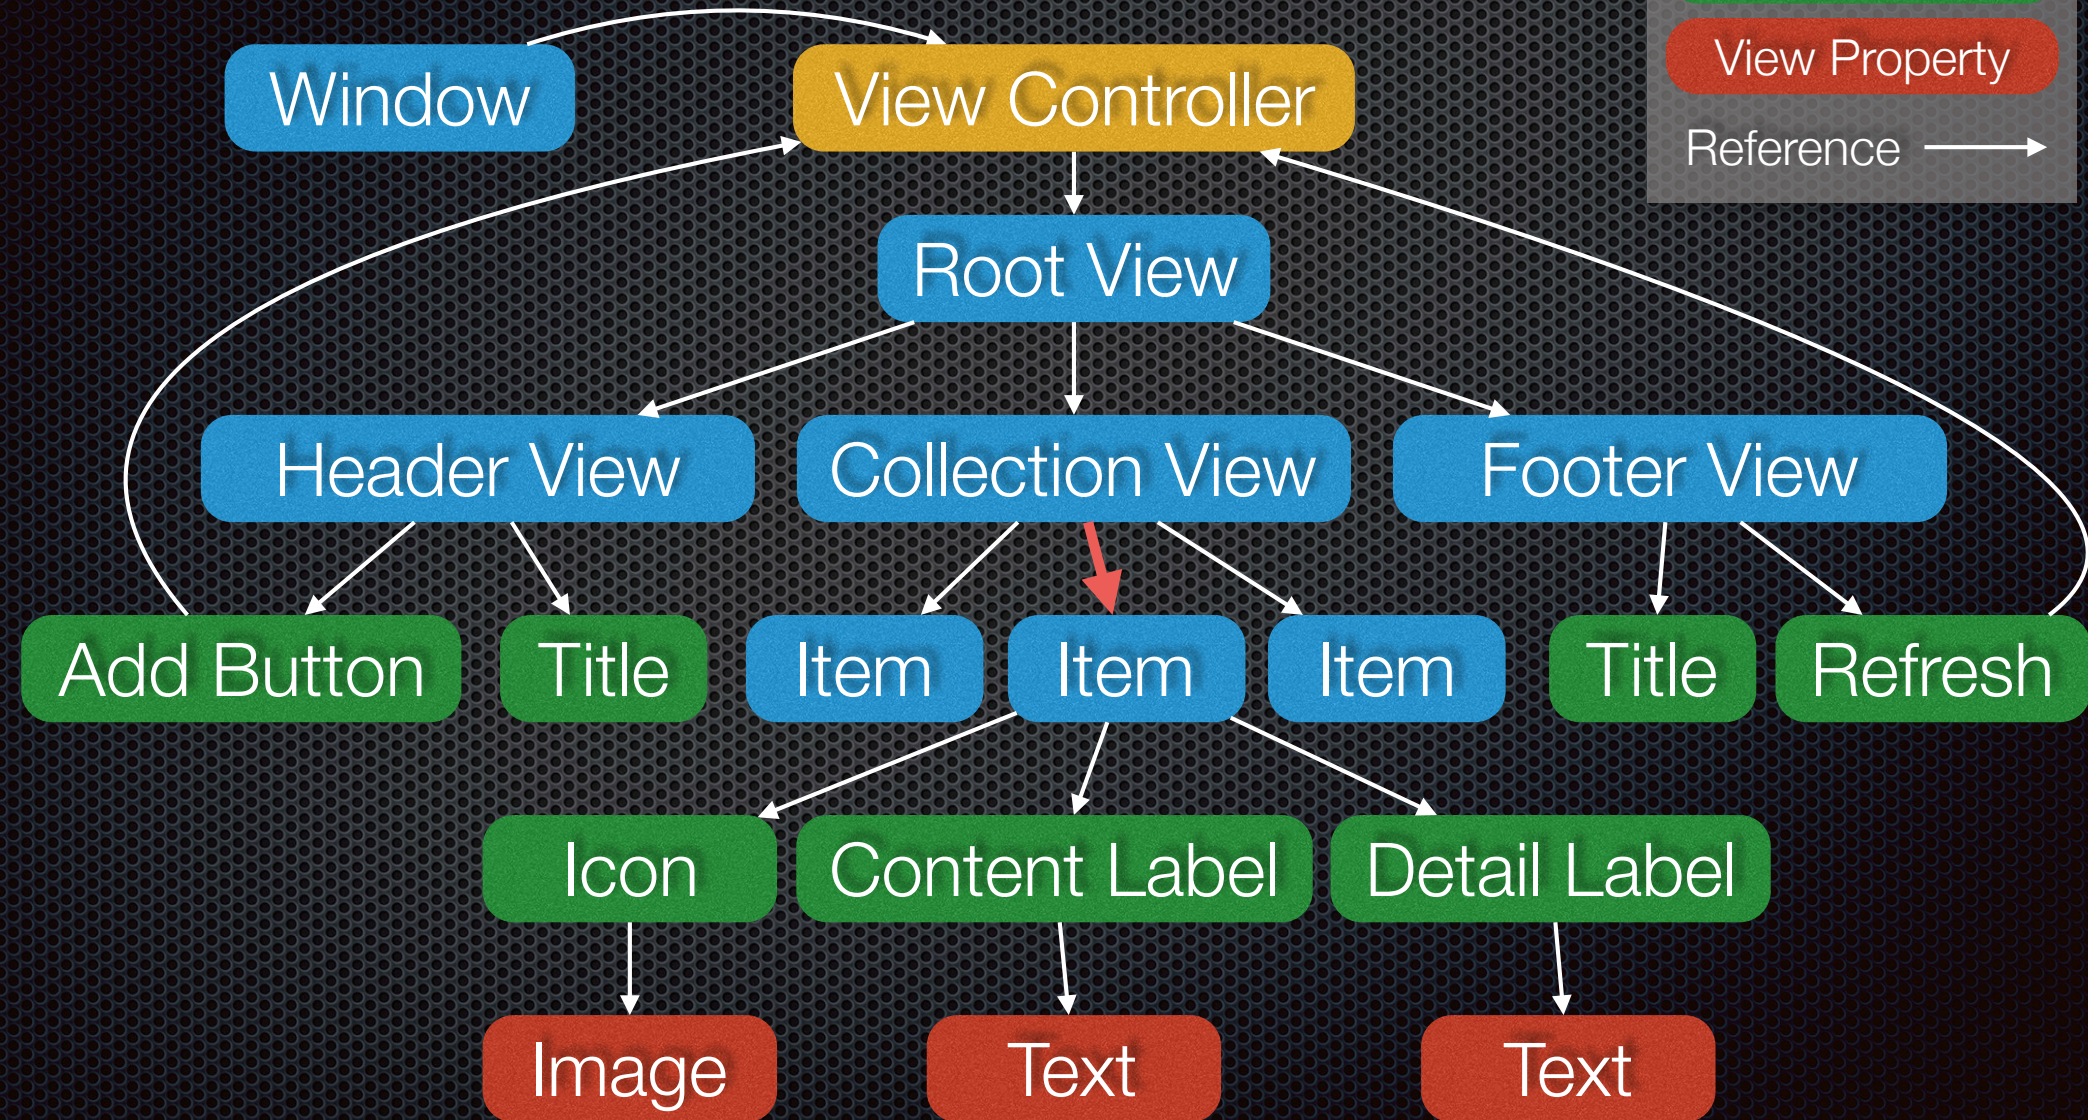

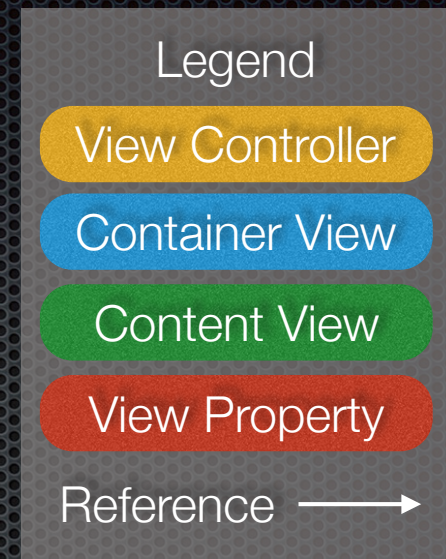

- Swift uses ARC to determine object **liveness**
- The **number of other objects** that have obtained a reference to an object is called its **reference count**
- When an object is created it is **referenced by the local variable it is assigned to** (or property if that is the case)
- As other objects obtain references the count increases
- Objects can remove references as well, reducing the count
 - Setting a property to nil or another object
 - A local variable **going out of scope**
- When an object has **no more references**, it is **deleted**

Strong and Weak

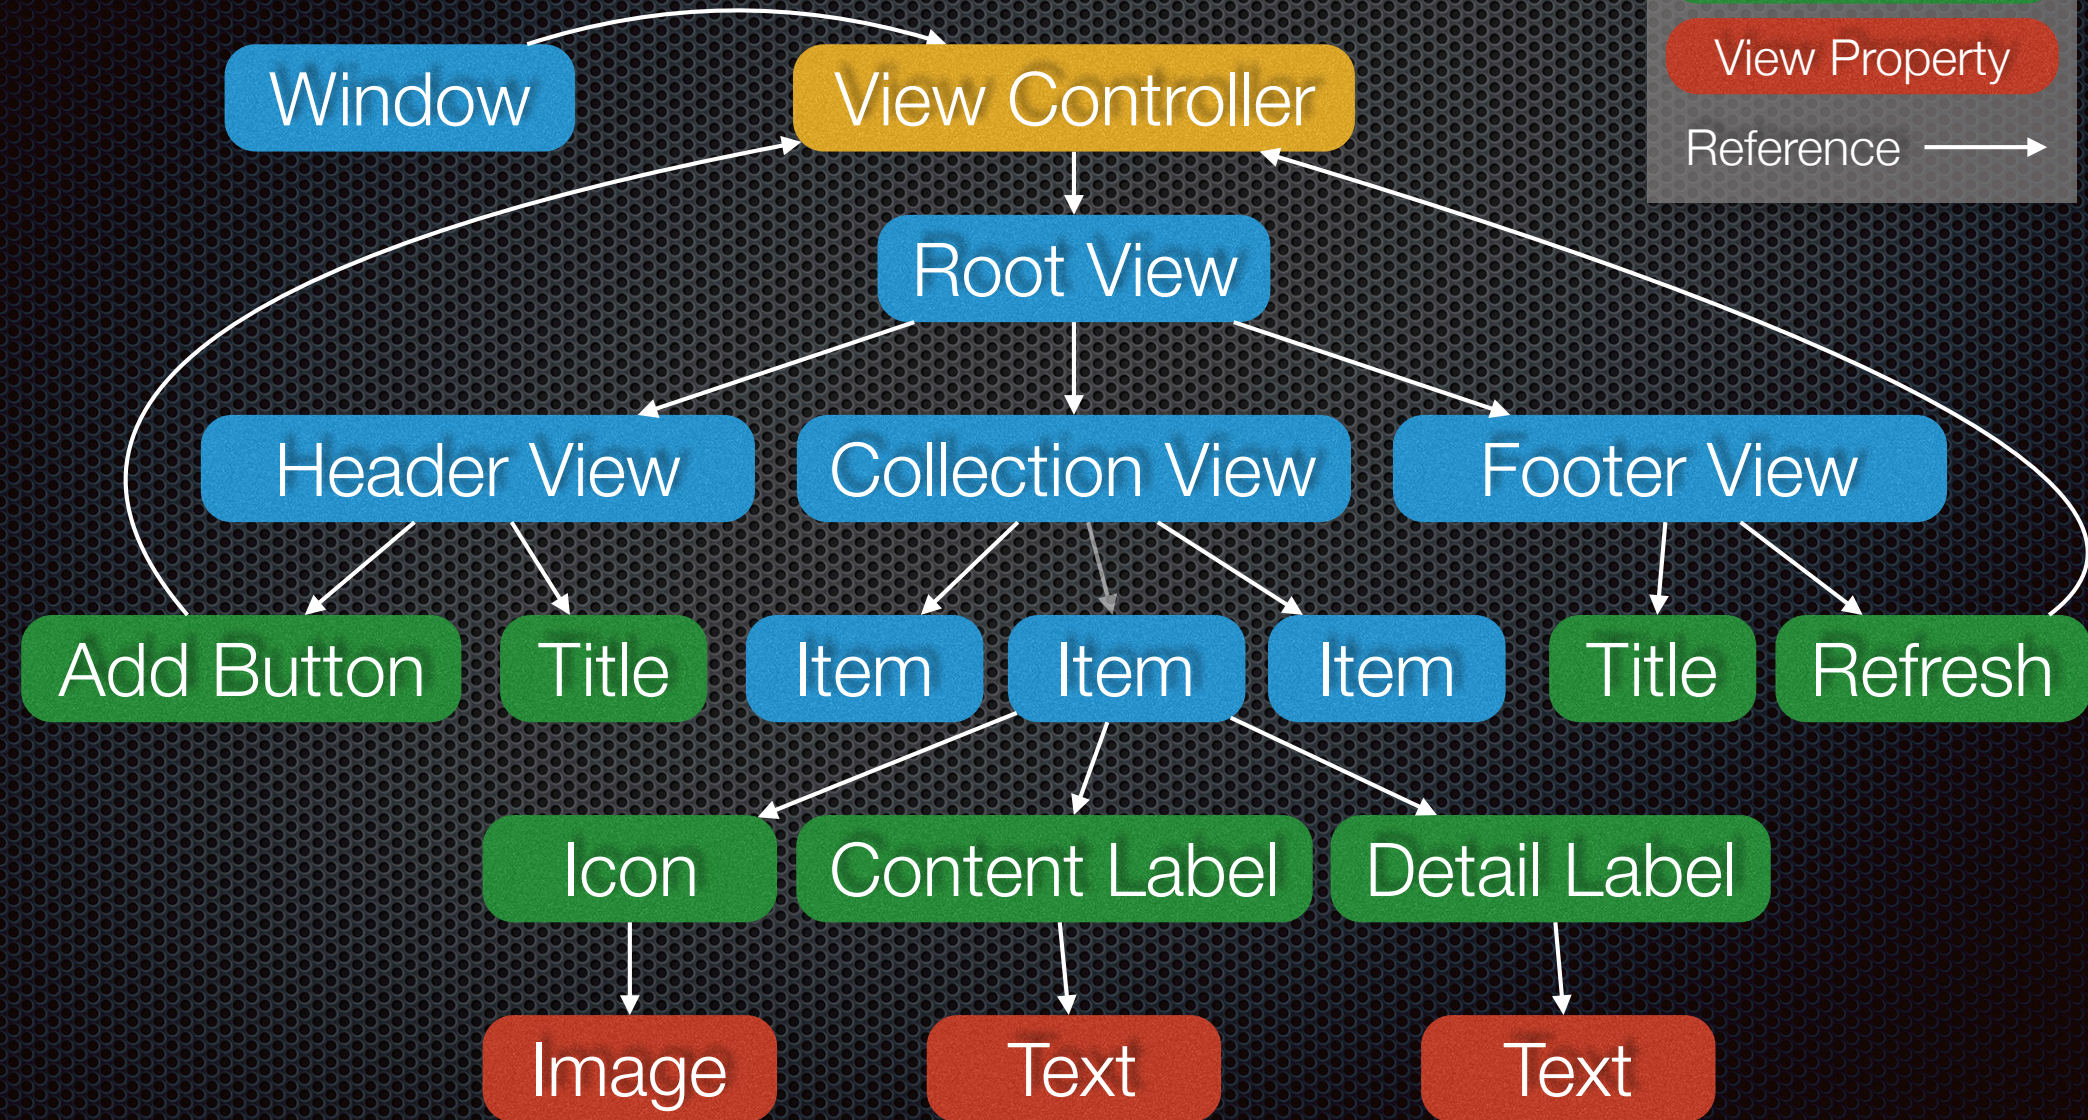

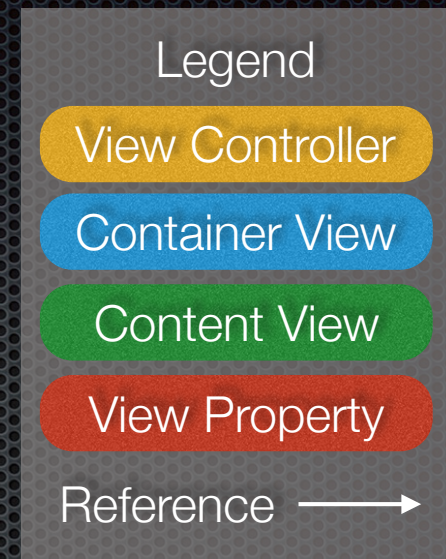

- Reference relationships can have the modifiers **strong** and **weak**
 - **strong** and **weak** properties (**weak** var someProperty: Double?)
 - **strong** and **weak** local variables (**weak** var localVar: Double?)
- Strong references (default) **increase** an object's reference count
- Weak references **do not increase** an object's reference count
- When the **last strong reference** to an object is removed, the object is **immediately deleted**, **deinit called**, and the **memory is reclaimed**
- Any weak references to the object that remain are **set to nil**
 - Because of this, weak properties and variables **must be optional**
