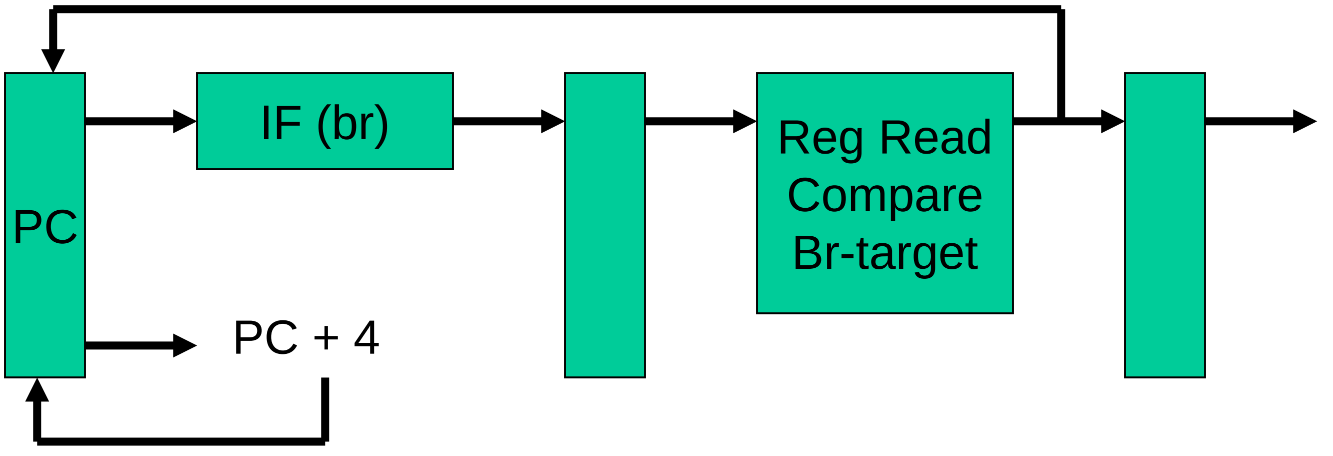
Lecture: Branch Prediction

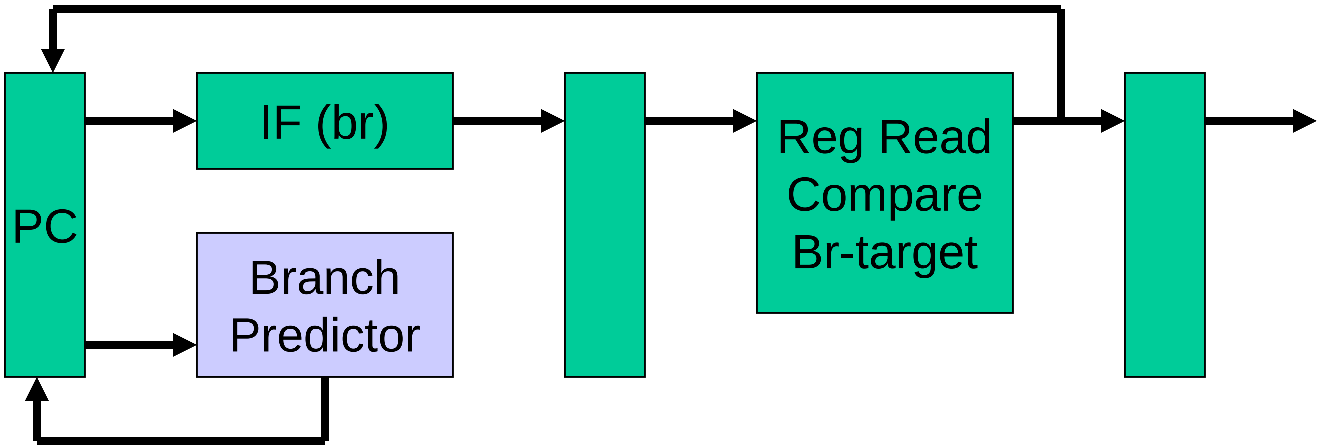
- Topics: branch prediction, bimodal/global/local/tournament predictors, branch target buffer (Section 3.3, notes on class webpage)

Pipeline without Branch Predictor



In the 5-stage pipeline, a branch completes in two cycles →
If the branch went the wrong way, one incorrect instr is fetched →
One stall cycle per incorrect branch

Pipeline with Branch Predictor



In the 5-stage pipeline, a branch completes in two cycles →
If the branch went the wrong way, one incorrect instr is fetched →
One stall cycle per incorrect branch

1-Bit Bimodal Prediction

- For each branch, keep track of what happened last time and use that outcome as the prediction
- What are prediction accuracies for branches 1 and 2 below:

```
while (1) {
      for (i=0;i<10;i++) {                    branch-1
          …
      }
      for (j=0;j<20;j++) {                    branch-2
         …
      }
}
```

2-Bit Bimodal Prediction

- For each branch, maintain a 2-bit saturating counter:
  if the branch is taken: counter = min(3,counter+1)
  if the branch is not taken: counter = max(0,counter-1)

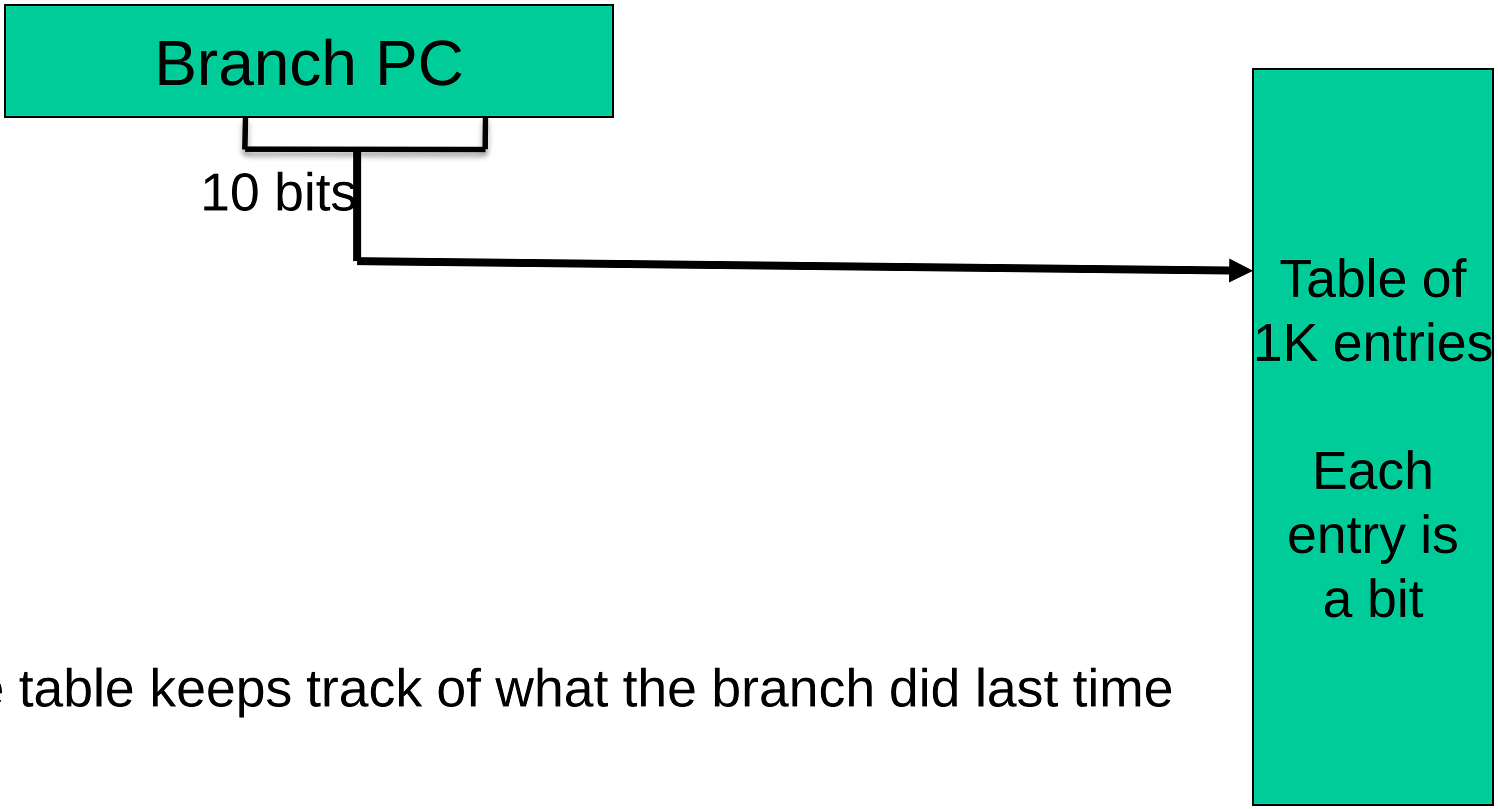
- If (counter >= 2), predict taken, else predict not taken

- Advantage: a few atypical branches will not influence the prediction (a better measure of "the common case")

- Especially useful when multiple branches share the same counter (some bits of the branch PC are used to index into the branch predictor)

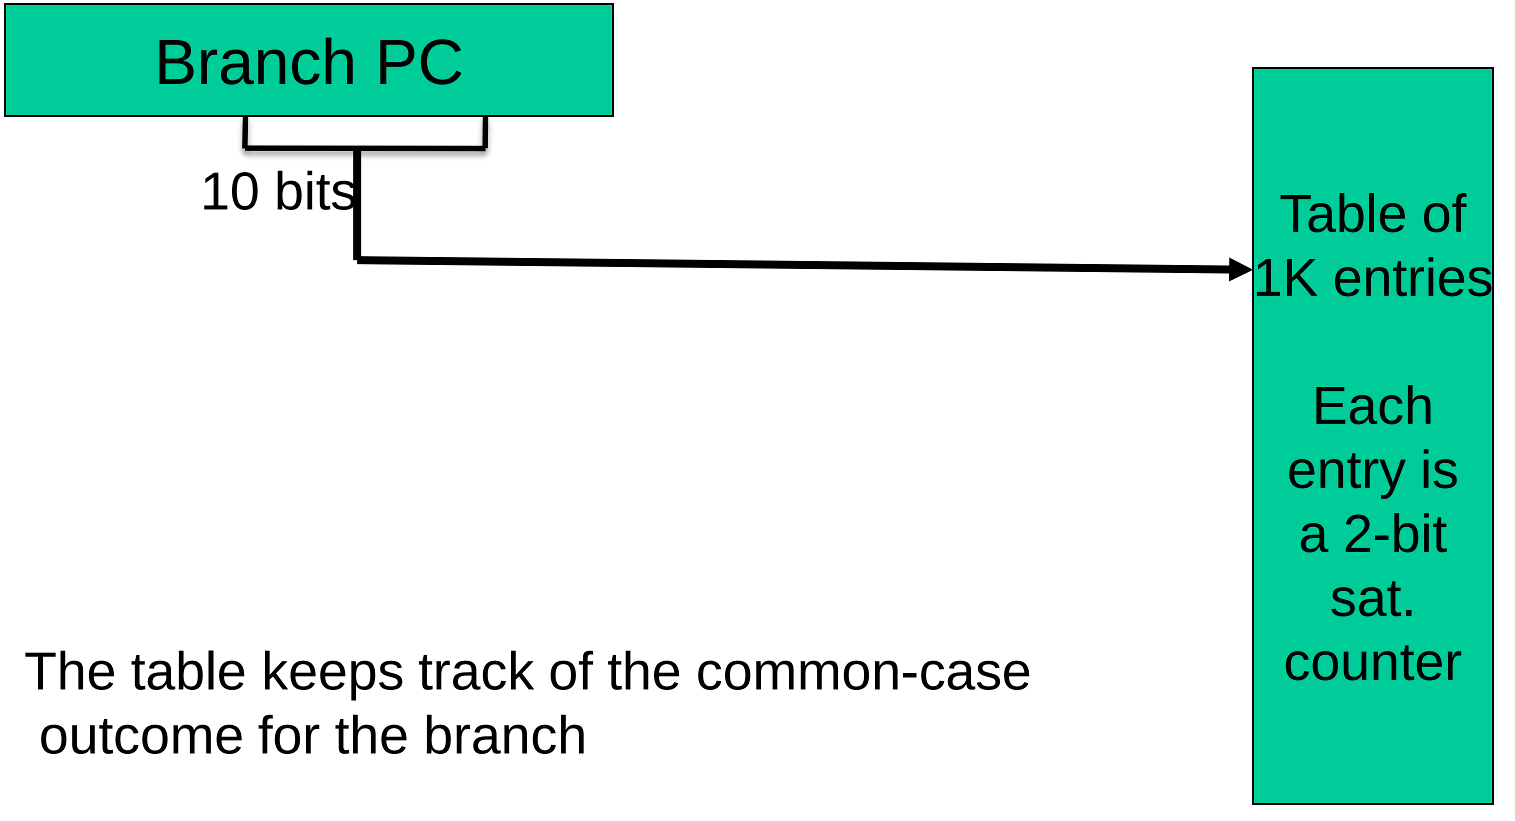
- Can be easily extended to N-bits (in most processors, N=2)

Bimodal 1-Bit Predictor



The table keeps track of what the branch did last time

Bimodal 2-Bit Predictor



The table keeps track of the common-case outcome for the branch

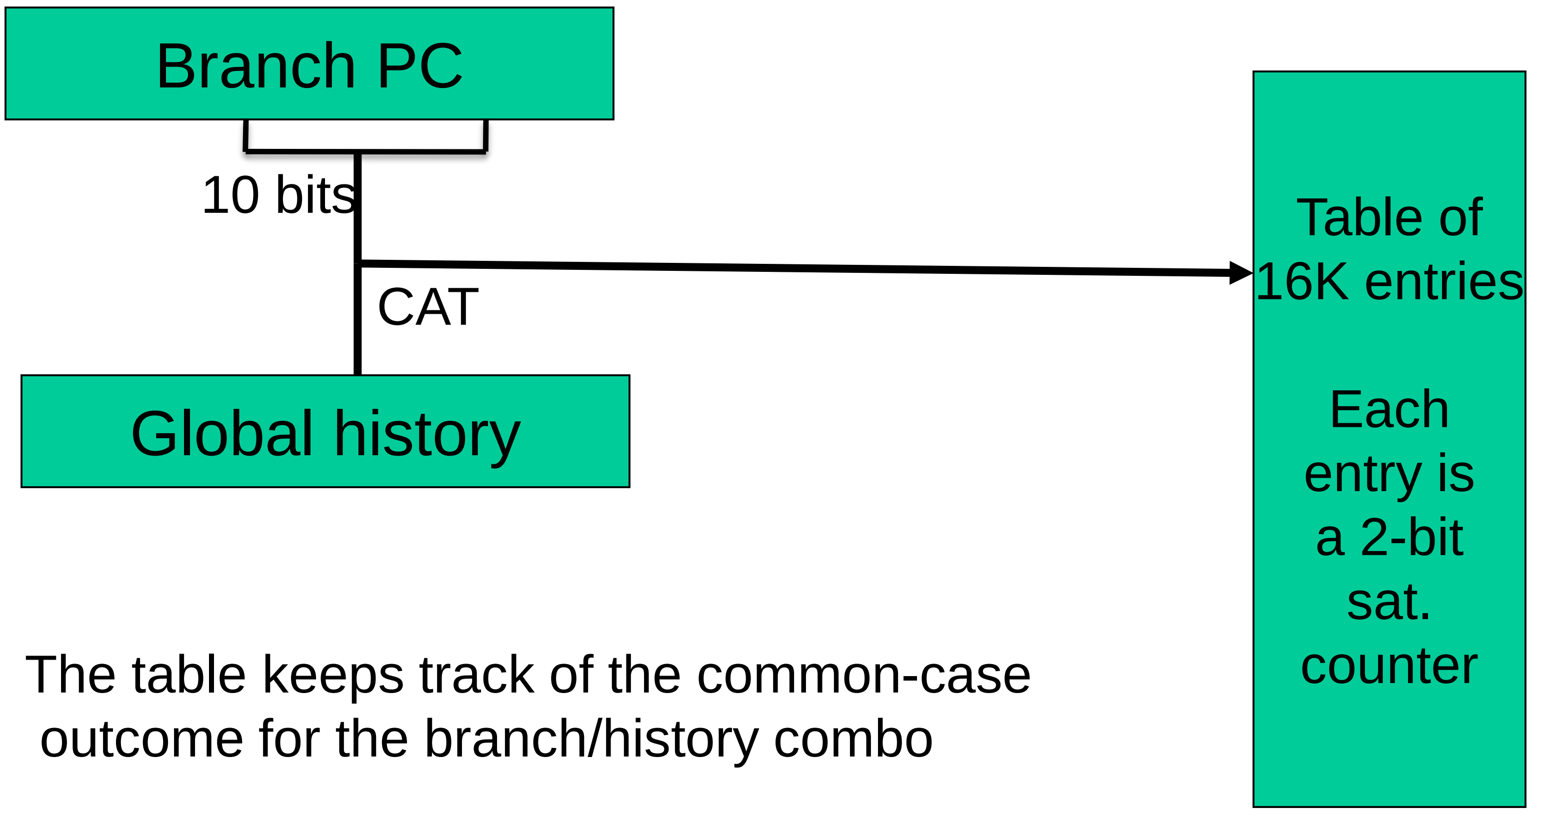
Correlating Predictors

- Basic branch prediction: maintain a 2-bit saturating counter for each entry (or use 10 branch PC bits to index into one of 1024 counters) – captures the recent "common case" for each branch

- Can we take advantage of additional information?
  - If a branch recently went 01111, expect 0; if it recently went 11101, expect 1; can we have a separate counter for each case?
  - If the previous branches went 01, expect 0; if the previous branches went 11, expect 1; can we have a separate counter for each case?

Hence, build correlating predictors

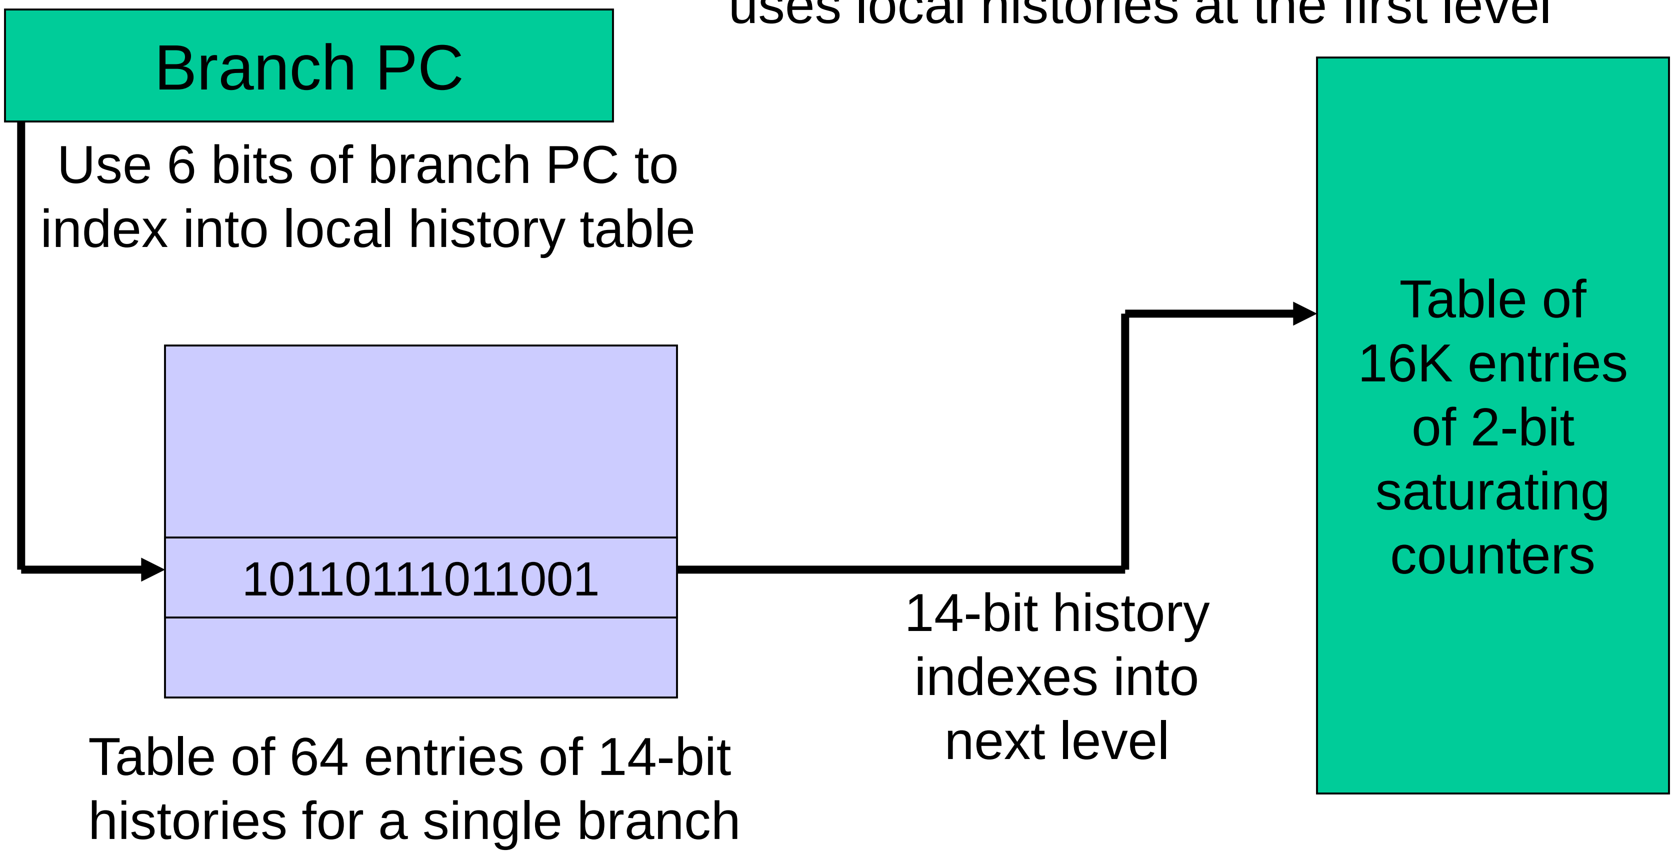
Global Predictor



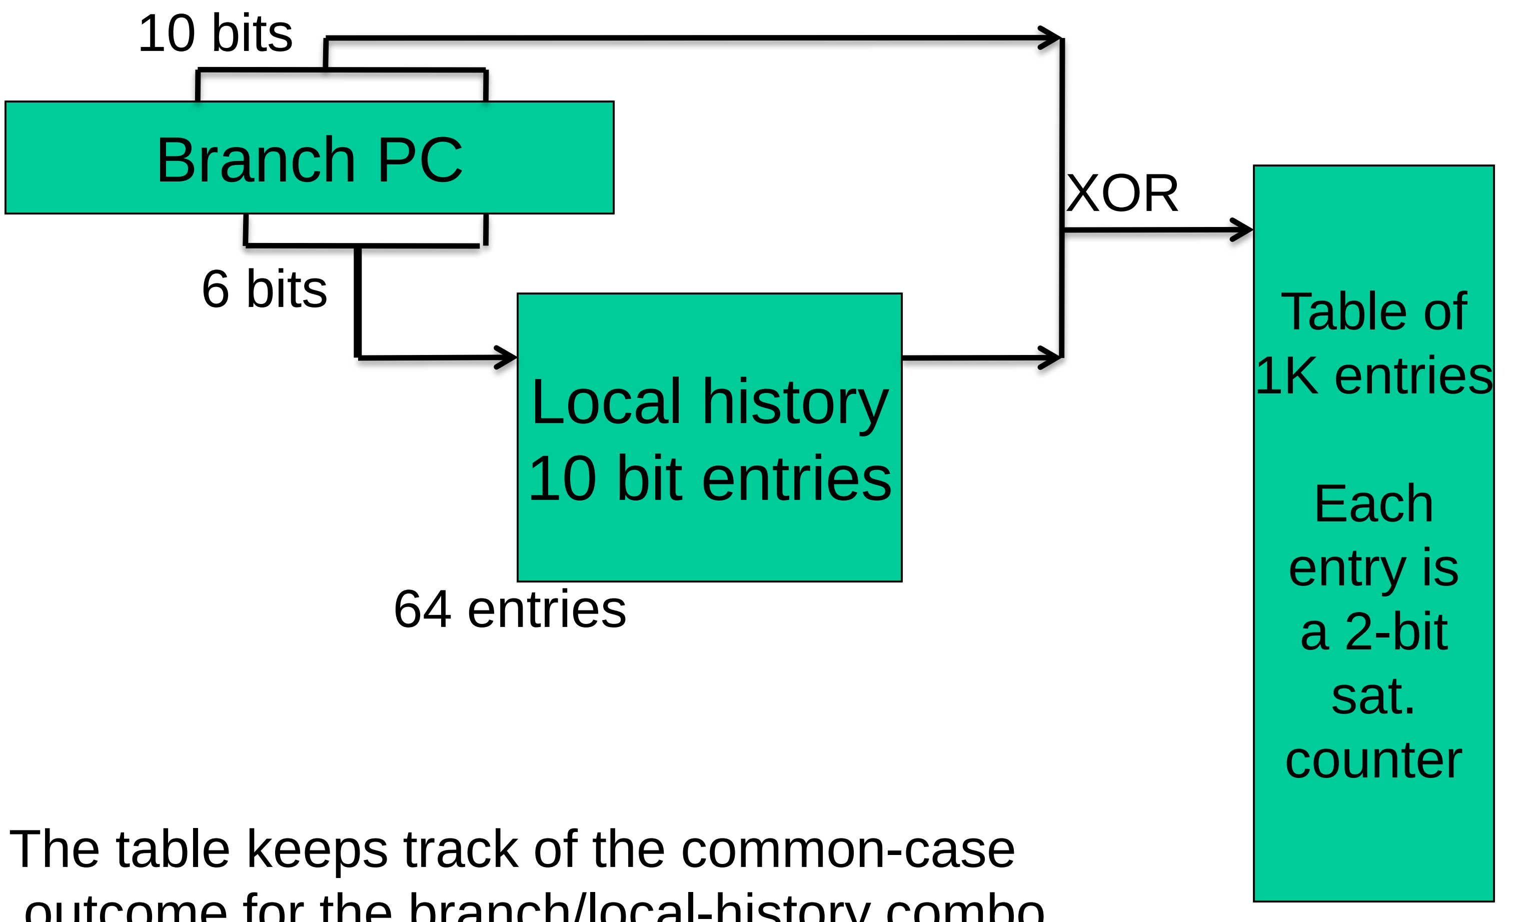
The table keeps track of the common-case outcome for the branch/history combo

Local Predictor

Also a two-level predictor that only uses local histories at the first level



Local Predictor



The table keeps track of the common-case outcome for the branch/local-history combo

Local/Global Predictors

- Instead of maintaining a counter for each branch to capture the common case,

→ Maintain a counter for each branch and surrounding pattern
→ If the surrounding pattern belongs to the branch being predicted, the predictor is referred to as a local predictor
→ If the surrounding pattern includes neighboring branches, the predictor is referred to as a global predictor

Tournament Predictors

- A local predictor might work well for some branches or programs, while a global predictor might work well for others

- Provide one of each and maintain another predictor to identify which predictor is best for each branch

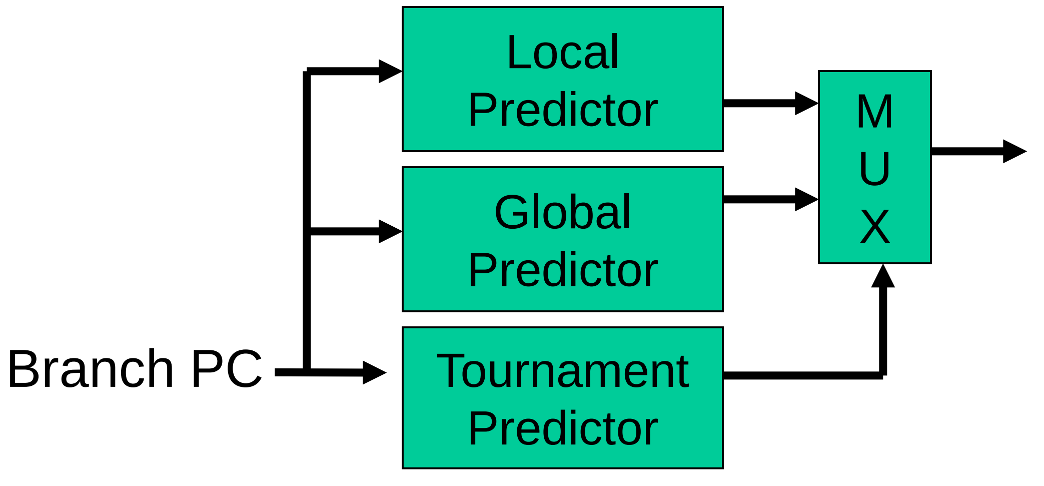


Table of 2-bit saturating counters

Alpha 21264:
1K entries in level-1
1K entries in level-2

4K entries
12-bit global history

4K entries

Total capacity: ?

Branch Target Prediction

- In addition to predicting the branch direction, we must also predict the branch target address
- Branch PC indexes into a predictor table; indirect branches might be problematic
- Most common indirect branch: return from a procedure – can be easily handled with a stack of return addresses

Problem 1

- What is the storage requirement for a global predictor that uses 3-bit saturating counters and that produces an index by XOR-ing 12 bits of branch PC with 12 bits of global history?

Problem 1

- What is the storage requirement for a global predictor that uses 3-bit saturating counters and that produces an index by XOR-ing 12 bits of branch PC with 12 bits of global history?

  The index is 12 bits wide, so the table has 2^{12} saturating counters. Each counter is 3 bits wide. So total storage = 3 * 4096 = 12 Kb or 1.5 KB

Problem 2

- What is the storage requirement for a tournament predictor that uses the following structures:
  - a “selector” that has 4K entries and 2-bit counters
  - a “global” predictor that XORs 14 bits of branch PC with 14 bits of global history and uses 3-bit counters
  - a “local” predictor that uses an 8-bit index into L1, and produces a 12-bit index into L2 by XOR-ing branch PC and local history. The L2 uses 2-bit counters.

Problem 2

- What is the storage requirement for a tournament predictor that uses the following structures:
  - a “selector” that has 4K entries and 2-bit counters
  - a “global” predictor that XORs 14 bits of branch PC with 14 bits of global history and uses 3-bit counters
  - a “local” predictor that uses an 8-bit index into L1, and produces a 12-bit index into L2 by XOR-ing branch PC and local history. The L2 uses 2-bit counters.

Selector = 4K * 2b = 8 Kb
Global = 3b * 2^14 = 48 Kb
Local = (12b * 2^8) + (2b * 2^12) = 3 Kb + 8 Kb = 11 Kb
Total = 67 Kb

Problem 3

- For the code snippet below, estimate the steady-state bpred accuracies for the default PC+4 prediction, the 1-bit bimodal, 2-bit bimodal, global, and local predictors. Assume that the global/local preds use 5-bit histories.

```
do {
    for (i=0; i<4; i++) {
        increment something
    }
    for (j=0; j<8; j++) {
        increment something
    }
    k++;
} while (k < some large number)
```

Problem 3

- For the code snippet below, estimate the steady-state bpred accuracies for the default PC+4 prediction, the 1-bit bimodal, 2-bit bimodal, global, and local predictors. Assume that the global/local preds use 5-bit histories.

```
do {
    for (i=0; i<4; i++) {
        increment something
    }
    for (j=0; j<8; j++) {
        increment something
    }
    k++;
} while (k < some large number)
```

PC+4: 2/13 = 15%

1b Bim: (2+6+1)/(4+8+1)
 = 9/13 = 69%

2b Bim: (3+7+1)/13
 = 11/13 = 85%

Global: (4+7+1)/13
 = 12/13 = 92%

(gets confused by 01111 unless you take branch-PC into account while indexing)

Local: (4+7+1)/13
 = 12/13 = 92%
